Question 1. Word Bank Matching (1 point each, 14 points)

For each statement below, input the letter of the term that is *best* described. Note that you can click each word (cell) to mark it off. Each word is used at most once.

A. — A/B Testing	B. — Agile development	C. — Alpha Testing	D. — Beta Testing
E. — Competent Programmer's Hypothesis	F. — Dynamic Analysis	G. — Formal Code Inspection	H. — Fuzz Testing
I. — Integration Testing	J. — Milestone	K. — Mocking	L. — Oracle
M. — Pair Programming	N. — Pass Around Code Review	O. — Perverse Incentive	P. — Priority
Q. — Race Condition	R. — Regression testing	S. — Risk	T. — Severity
U. — Static Analysis	V. — Streetlight Effect	W. — Triage	X. — Unit Testing
Y. — Waterfall Model

following approach. They will release the new feature to half of their users, who were selected randomly. After two weeks, they will collect feedback from all users through a survey.

Q1.9: V

MoonChips inc. has recently been made aware of a bug that causes their links to be unclickable. Fanghao is trying to fix this bug, and looks over recently made changes, as those changes were fresh in Fanghao's mind. The bug was ultimately caused by an obscure line elsewhere, where the URL is set to null.

Q1.10: N

Veecsa co. requires all changes to have another developer's approval, before merging to the codebase. This work can be done offline too, without them meeting in person.

Q1.11: Q

Max is writing an application (which is implemented as a multi-threaded program) for students to reserve a study room. Unfortunately a bug allows multiple people to sign up for the same study room at the same exact time.

Q1.12: P

Software development tool, Phabricator assigns labels of "Unbreak Now!", "High", "Normal", "Low", and "Lowest" to indicate the importance or urgency of fixing a defect.

Q1.13: H

A new streaming service company GlazeBook wants to test their new chatbot. To do this, they randomly generate 100,000 inputs with valid and invalid characters, and see if the chatbot responds appropriately.

Q1.14:

Gogo inc. is trying to create a social media app. They have created the login and the dashboard and want to test how they work together to ensure that users will not have any issues navigating between the two pages.

Question 2. Code Coverage (20 points)

You are given the following code. (Please scroll down to see the all functions.) Assume that statement coverage applies only to statements marked STMT_#. In this question, we consider the entire program when calculating coverage. The code starts at main(), but even if some methods are not executed during the program execution for a given input, we still consider coverage with respect to all 8 STMTs.

```
1 void checkStrings(string a, string b) {
       if (a != "") {
 2
 3
           STMT_1;
           if (strlen(a) > 4) {
 4
 5
               STMT_2;
 6
           }
 7
           STMT_3;
 8
       }
 9
       else {
10
           return;
11
       }
12
13
       if (a[0] != b[0]) {
14
           if (a[0] == 'b') {
15
               STMT_4;
16
           }
17
           STMT_5;
18
       }
19 }
20
21 int sumDigits(int x) {
22
       int s = 0;
23
       while (x > 0) {
24
           STMT_6;
25
           s = s + (x % 10); // Note: '%' is the modulo operator
26
           x = x / 10;
27
```

```
28
       return s;
29 }
30
31 int main(string a, string b, int x, int y) {
32
       int s1 = sumDigits(x);
33
       int s2 = sumDigits(y);
34
       if (s1 == s2 && s1 != 0 && s2 != 0) {
35
           STMT_7;
           checkStrings(a, b);
36
       }
37
       STMT_8;
38
39
40
       return 0;
41 }
42
```

(a) (3 points)

Give a test input for main() that achieves EXACTLY 25% statement coverage.

In the context of this question, you have to pick inputs from the following strings: { red, blue, green, black, brown, pink } and the following ints: { 4444, 97, 790, 2462, 718, 1091 }.

This is important.

Please write your answer in the following format, as a call to main(), because an auto-grader will be used to facilitate grading. Ex: main('blue', 'blue', 97, 97)

If no such input exists, write IMPOSSIBLE (all capital letters).

```
Your answer here.
```

ANSWER: 25%: Any input where the sum of the two ints's digits doesn't equal each other. STMT_6, STMT_8 Different students were presented with different coverage targets. Some example answers include:

- 25: main('red', 'green', 1091, 718)
- 50: IMPOSSIBLE
- 75: main('black', 'blue', 4444, 97)

(b) (3 points)

Give a test input to main() that achieves the **lowest** statement coverage. Also, what is its coverage?

You can use any string or integer for the input parameters. No need to restrict to those in (a).

This is important.

Please enter your answer as a call to main() followed by the statement coverage (as a percentage), in the following format. Ex: main('blue', 'blue', 97, 97) 75%

```
Your answer here.
```

ANSWER: 12.5%: Both x = 0 and y = 0.

Different students were presented with different questions. Some example answers include:

- Highest: 100%. main('black', 'pink', 4444, 97) x and y's digits have the same sum, a is at least a 5 letter word starting with 'b'. a and b start with different letters.
- Lowest: 12.5%. main('black', 'blue', 0, 0) Both x and y have to be 0.

(c) (2 points)

In regards to path coverage, how many paths does the input you gave in (b) cover?

This is important.

Please enter **ONLY** the number of paths (as a number, like 4) in the text box below.

Your answer here.

ANSWER: 1, one input corresponds to one path

(d) (2 points)

What is the minimum number of test cases needed to get exactly **80%** branch coverage?

For this question, we only consider branches created by the 5 if-statements (we do not consider branches from loops), meaning there are 10 branches total.

This is important.

Please enter **ONLY** the number of test cases (as a number, like 1).

Your answer here.

ANSWER: 3 Test Cases

Different students were presented with different coverage targets. Some example answers include:

- 50%: 1 Test Case
- 60%: 2 Test Cases
- 80%: 3 Test Case

```
1 int main (string a, string b, int x, int y) {
 2
      int s1 = sumDigits(x);
 3
      int s2 = sumDigits(y);
 4
 5
      STMT_7;
 6
      checkStrings(a, b);
 7
      STMT_8;
 8
 9
      return 0;
10 }
11
```

(e) (4 points)

Suppose main() in the previous questions is changed to the main() **above**. The differnce is that, now, STMT_7 and checkStrings(a,b) are no longer within an if-statement and instead are always executed.

How does the **highest** possible branch coverage for a single test input change, if at all? Recall that we only consider branches created by if-statements. Hint: After the change, there are now 4 if-statements, meaning that there are 8 branches.

This is important

Please enter the **old highest** coverage and **new highest** coverage (both as percentages) on **one line seperated by a comma** (space doesn't matter). For example: 10%, 10%

Your answer here.

ANSWER: 50%, 50%

Different students were presented with different questions. Some example answers include:

- **Old Lowest:** 10%. x and y have different sums or the sum is 0. **New Lowest:**12.5%. a = ", results in checkStrings() returning.
- **Old Highest:** 50%. x and y have the same sum, a is at least a 5 letter word starting with b. a and b start with different letters. **New Highest:**50%. a is at least a 5 letter word starting with b. a and b start with different letters.

(f) (6 points)

A company is attempting to locate bugs in their software by maximizing one coverage metric.

For **each** of the following metrics (branch coverage, statement coverage, path coverage), discuss one benefit of maximizing it and one area where it falls short.

Please limit your entire answer to at most 6 sentences. We suggest you use two sentences for each metric (one for the benefit, and one for the shortcoming).

Your answer here.

- Question 1
- Question 2
- Question 3
- Question 4
- Question 5
- Question 6
- Extra Credit
- Pledge & Submit

ANSWER: Student answers will vary

Statement coverage

- Benefit: Helps identify 'dead' or inaccessible code
- **Drawback:** It doesn't really matter how the line is executed. We could give it a bunch of random input, with no reasoning, to try to maximize the coverage. Least thorough out of the three.

Branch Coverage

- **Benefit:** Testing all branches will lead to 100%% statement coverage. Ensure all branches and their alternatives have been run.
- **Drawback:** Doesn't look at how an input interacts with the entire code, only different branches. A lot of tests targeting different branches would have the same coverage as a few tests targeting many branches.

Path Coverage

- **Benefit:** Test all ways that some input(s) could run through the entire code. Most thorough out of the three. Inputs must be chosen intentionally
- Drawback: Can be tedious to implement especially for larger pieces of software

Question 3. Short Answer (25 points)

For each of the two bugs below, please describe (1) an example where the bug would have high severity and (2) a scenario where the bug would have low severity. Explain why in both cases.

Please limit your answer to at most 4 sentences, for each bug.

(a) (3 points)

A bug that causes the color of text to change.

Your answer here.

ANSWER:

Possible answers (answers may vary):

- Low severity: The color of text in the "Terms and Conditions" section on a website changes. While the change is noticeable, it doesn't impact the readability or understanding of critical information, making it a low-severity issue. (Answer explains how the color of text doesn't greatly affect main functionality 1.5 pts)
- High severity: The color of text in an error message indicating a critical system failure changes. In this case, the altered color may mislead users about the severity of the issue, potentially causing misunderstanding and hindering prompt corrective action, making it a high-severity bug. (Answer explains how the color of text greatly affects main functionality 1.5 pts)

(b) (3 points)

A bug that causes your app to occasionally close unexpectedly.

Your answer here.

ANSWER:

Possible answers (answers may vary):

- Low severity: The weather app closes. You can reopen the app and check the weather, nothing is lost, just a few seconds of your time. Users won't be too upset. (Answer explains how unexpectedly closing doesn't greatly affect main functionality 1.5 pts)
- High severity: Any situation where there is lost or unsaved important work or progress. For example, Microsoft Word closes (without autosave) and you lose your essay. Another example, you are playing a video game for 3 hours without saving, and it closes out, making you lose all that progress. (Answer explains how unexpectedly closing affects main functionality 1.5 pts)

minutes remaining

Each of the following questions (c)-(e) gives a pair of concepts. It can be a pair of techniques, or a pair of tools, or a pair of processes, etc. Given a pair, please explain why the first one **could** be better (e.g., more likely to succeed and reduce software engineering effort, or to improve software engineering outcomes) than the second. Your explanation may depend on the specific pair given. For full credit, please also briefly describe a situation to illustrate why the first is better than the second. Note that your answer should not only explain why the first may be good, but also why the second may not be good. For each question, please use no more than four sentences.

(c) (3 points)

Integration Testing vs. Regression Testing

Your answer here.			

ANSWER:

Possible answer:

• Integration Testing better: In a large e-commerce platform with numerous interconnected modules (e.g., user authentication, inventory management, and payment processing), integration testing is superior. It excels in detecting defects that arise from the collaboration of these diverse components. For instance, an integration test can reveal issues where a successful user login doesn't synchronize correctly with the inventory system, ensuring a seamless end-to-end functionality that regression testing might not fully capture.

(d) (3 points)

Alpha Testing vs. A/B Testing

Your answer here.

ANSWER:

Possible answer:

• Alpha testing better: You make a major change to the structure of your product (or you develop a completely new product). This product needs to be tested to see if it works correctly as the structure has been largely changed. Alpha testing allows the developers to test it to make sure it works as intended before releasing it to the public. A/B testing could force an unfinished/not working product out which might scare away customers. It also isn't very useful, because if you spent all those resources making this major change, you are probably not going to backtrack on those changes.

(e) (3 points)

Unit Testing vs. Static Dataflow Analysis

Your answer here.

ANSWER:

Possible answer:

• Unit tests better: You already know what part of the code is buggy and have attempted to rewrite it. Static dataflow analysis could take an unnecessary amount of time and resources, and it won't point out if the buggy section has been fixed.

(f) (5 points)

Suppose Test A has lower statement coverage than Test B.

Support or Refute: It is impossible for Test A to expose more bugs than Test B. If supporting, explain why it is impossible. If refuting, give a specific example or situation of where Test A could expose more bugs than Test B. Please limit your answer to at most four sentences.

Your answer here.

ANSWER:

• Choose Refute: For a test to perform well with statement coverage, it only has to run a certain line. Even if the line is potentially buggy on certain inputs, the test doesn't have to expose the bug to perform well with statement coverage. For example, let's say there is only one potential bug in a file, a division by 0 error. If test B only gives inputs that result in dividing by a non-zero number, then that bug will never be exposed, even if test B executes that line. Test A executes less statements, but if it executes the buggy line and the input results in a division by 0, then test A exposes that line, and thus exposes more bugs than test B. (Choose Refute - 2pts, Explanation - 3pts)

(g) (5 points)

As a software engineer at 481Company, you are responsible for developing rapid changing software (which requires to be constantly updated). Your coworker Darwin Nunez suggests that the company switches from agile development to the waterfall development model due to its simple process. Do you agree or disagree with Darwin? Explain which development methodology you believe 481Company should follow, and explain why it is better than the other methodology. Please limit your answer to at most four sentences.

Your answer here.

ANSWER:

• Disagree. 481company should use Agile development. 481company deals with changes often, so we need a more adaptable and flexible approach to be able to deal with these changes at any time in our development cycle. While the waterfall approach is more simple, it is also more rigid and it is more costly and difficult to respond to changes down the process. It also gives us less releases of our rapidly changing software to the public. (Choose Disagree - 2pts, Explanation - 3pts)

Question 4. Mutation Testing & Invariants (15 points)

The following function is_prime checks whether a given integer n is a prime number. While the following code shows a total of five first-order mutants (see comments), in this question, you will only be asked to analyze a specific subset of them.

```
1 def is_prime(n):
       if n < 2:
                                         # Mutant 1: if n <= 2:
 2
 3
            return False
 4
 5
                                         # Mutant 2: i = 1
       i = 2
       while i * i \le n:
 6
                                         # Mutant 3: while i*i < n:</pre>
                                         # Mutant 4: if n % i == 1:
 7
            if n % i == 0:
 8
                return False
 9
                                         # Mutant 5: i += 2
            i += 1
10
11
       return True
12
```

(a) (6 points)

Complete the table below by indicating whether or not each test case kills **Mutants 2 and 5**. Note that column oracle shows the ground-truth (i.e., desired) return value of is_prime(n). (K: Killed, N: Not killed.)

test case	n	oracle	Mutant 1	Mutant 2	Mutant 5
1	n=2	Т	К	\circ K \circ N	\bigcirc K \bigcirc N
2	n=4	F	N	\circ K \circ N	\bigcirc K \bigcirc N
3	n=5	Т	N	\circ k \circ N	\circ k \circ N

ANSWER:

test case	n	oracle	Mutant 1	Mutant 2	Mutant 5
1	n=2	Т	К	К	N
2	n=4	F	N	N	N
3	n=5	Т	N	К	N

(b) (2 points)

What is the mutation adequacy score for test cases 1-3 from (a), using **only Mutant 1**?

This is important. To facilitate auto-grading, please write your answer in the following format. Round the score to two decimal points and write **ONLY** the score in the box. For example: 0.12

Your answer here.

ANSWER: 1.00.

Mutation score is calculated as killed/totall. We only have Mutant 1, and it is killed by n=2, so 1/1=1.00.

(c) (2 points)

What is the mutation adequacy score for test cases 1-3 from (a), using **Mutants 1, 2, and 5**?

This is important. To facilitate auto-grading, please write your answer in the following format. Round the score to two decimal points and write **ONLY** the score in the box. For example: 0.12

Your answer here.

ANSWER: 0.67.

Killed mutants: 1, 2, so 2/3=0.67.

(d) (2 points)

Please write (1) one advantage and (2) one disadvantage, of higher-order mutation (i.e., multiple mutations per mutant). Limit your entire answer to at most two sentences. We suggest you allocate one sentence to advantage and one to shortcoming.

Your answer here.

ANSWER: Open question.

Pros can be: more realistic faults, reduced number of mutants, etc.

Cons can be: end up being killed by everything, reduced clarity in test results, etc.

(e) (3 points)

Consider the following three invariants for is_prime. Each invariant is evaluated right after the function terminates. In this quesiton, we define an invariant to be valid, if it always holds (i.e., evaluated to True) for all positive integers n (i.e., the input to is_prime).

For each invariant, please indicate whether or not it is valid, and if yes, whether the invariant can be falsifed by any of the Mutants 1-5.

Invariant 1: i is undefined || (n%i==0)

- A) Invalid.
- O B) Valid. At least one of the Mutants 1-5 can falsify it.
- C) Valid. None of the Mutants 1-5 can falsify it.

Invariant 2: i is undefined || (i <= n+1)</pre>

ANSWER: Choose A). Invalid. n=3 can falsify it.

- A) Invalid.
- O B) Valid. At least one of the Mutants 1-5 can falsify it.
- O C) Valid. None of the Mutants 1-5 can falsify it.

ANSWER: Choose C). Valid. None of the mutants can falsify it.

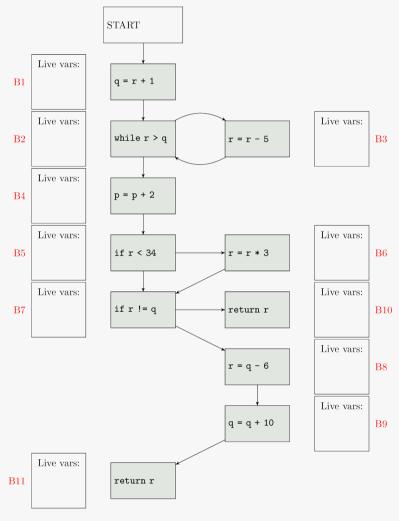

Invariant 3: i is undefined || (i >= 2)

- A) Invalid.
- B) Valid. At least one of the Mutants 1-5 can falsify it.
- O C) Valid. None of the Mutants 1-5 can falsify it.

ANSWER: Choose B). Valid. Mutant 2 can falsify it, n=1.

Question 5: Dataflow Analysis (11 points total)

Consider a *live variable dataflow analysis* for three variables, p, q, and r used in the control-flow graph below. We associate with each variable a separate analysis fact: either the variable is (1) possibly read on a later path before it is overwritten (live), or (2) it is not (dead). We track the set of live variables at each point: for example, if p and q are alive but r is not, we write {p, q}. The special statement return reads, but does not write its argument. In addition, if and while read, but do not write all of the variables in their predicates. (You must determine if this is a forward or backward analysis.)

(1 point each) For each basic block B1 through B11, write down the list of variables that are live *right before* the start of the corresponding block in the control flow graph above. Please list only the variable names in lowercase without commas or other spacing (e.g., use either ab or ba to indicate that a and b are alive before that block).

```
B2
                                                          B3
                                                                                       B4
B1
                                                         ANSWER: {'r',
                                                                                      ANSWER: {'r', 'q',
                            ANSWER: {'r', 'q',
                             'p'}
                                                         'p'}
                                                                                      'p'}
ANSWER: { 'r', 'p'}

ANSWER: { 'r', 'q'}
                                                                                      ANSWER: {'q'}
                             B10
                                                         B11
                            ANSWER: {'r'}
ANSWER: { 'r', 'q'}
                                                         ANSWER: {'r'}
```

Question 6. Dynamic Analysis (15 points)

You have developed a dynamic analysis tool, called Marbles, that aims to identify potential memory leaks.

Marbles works by tracking and logging memory allocations and deallocations during program execution. The program under analysis can be run multiple times simultaneously at different speeds, with each execution being assigned with a unique thread id number (for example, Thread 1). Marbles logs information about each memory operation, including the allocated memory address, deallocated memory address (if applicable), size of allocated memory, and the thread id.

However, Marbles can be buggy while it is analyzing programs, causing it to produce false positives and/or false negatives in the log files.

Recall the following:

A false positive occurs when a tool incorrectly predicts the presence of a condition or event that is not actually present. A *false negative* occurs when a tool incorrectly predicts the absence of a condition or event that is actually present.

In what follows, you will see three different programs. We have run Marbles on all of them. The log file for each program is also shown below. For each program, you will be asked to determine if Marbles would report a memory leak based on the Marbles log file. In addition, you will also be asked to determine whether Marbles has incurred any false positives/negatives during the logging process.

Using this information, answer the following subquestions (a) - (e).

NOTE: You may need to scroll down on some of the code snippets to view the full program and/or log file.

```
void p1() {
    // Dynamically allocates a pointer (4 bytes)
    int* ptr = new int;
    *ptr = 42;
}
Marbles log file:
Thread 1: Allocate 4 bytes at address 0x6000
Thread 2: Allocate 4 bytes at address 0x6100
```

(ai) (1 points) **True / False**: Marbles would report a memory leak for p1, based on the log file.

○ True

False

ANSWER: True Code does not deallocate memory and Marbles reports this correctly.

(aii) (1 points) **True / False**: Marbles incurred a false positive or false negative for p1, during its logging process.

True

False

ANSWER: False

No false positives/negatives. Marbles works correctly.

```
void p2() {
    // Dynamically allocates a new buffer (100 bytes), a c-style array
    char* buffer = new char[100];
    // Deallocates buffer
    delete[] buffer;
    // Dynamically allocates a new buffer (50 bytes)
    buffer = new char[50];
}
Marbles log file:
Thread 1: Allocate 100 bytes at address 0x6000
Thread 2: Allocate 100 bytes at address 0x6100
Thread 2: Deallocate 100 bytes at address 0x6100
Thread 3: Allocate 100 bytes at address 0x6200
Thread 3: Deallocate 100 bytes at address 0x6200
Thread 2: Allocate 50 bytes at address 0x6400
Thread 1: Deallocate 100 bytes at address 0x6000
Thread 3: Allocate 50 bytes at address 0x6500
Thread 1: Allocate 50 bytes at address 0x6300
```

```
(bi) (1 points) True / False: Marbles would report a memory leak for p2, based on the log file.
```

○ True

○ False

ANSWER: True

Code does not deallocate memory and Marbles reports this correctly.

(bii) (1 points) **True / False**: Marbles incurred a false positive or false negative for p2, during its logging process.

- True
- False

ANSWER: False

No false positives/negatives. Marbles works correctly.

```
void p3() {
    // Dynamically allocate array1 (20 bytes)
    int* array1 = new int[5];
    // Dynamically allocate array2 (12 bytes)
    int* array2 = new int[3];
    for (int i = 0; i < 2; ++i) {
        // Dynamically allocates a new tempArray (40 bytes)
        int* tempArray = new int[10];
        // Deallocates the new tempArray
        delete[] tempArray;
    }
    // Deallocate array1 and array2
    delete[] array1;
    delete[] array2;
}
Marbles log file:
Thread 1: Allocate 20 bytes at address 0x6000
Thread 1: Allocate 12 bytes at address 0x6100
Thread 2: Allocate 20 bytes at address 0x6400
Thread 2: Allocate 12 bytes at address 0x6500
Thread 2: Allocate 40 bytes at address 0x6600
Thread 1: Allocate 40 bytes at address 0x6200
Thread 2: Deallocate 40 bytes at address 0x6600
Thread 1: Deallocate 40 bytes at address 0x6200
Thread 2: Allocate 40 bytes at address 0x6700
Thread 2: Deallocate 40 bytes at address 0x6700
Thread 1: Allocate 40 bytes at address 0x6300
Thread 1: Deallocate 40 bytes at address 0x6300
```

(ci) (1 points) **True / False**: Marbles would report a memory leak for p3, based on the log file.

- True
- False

ANSWER: True

Code does deallocate memory, but Marbles does not show any deallocation logs for array1 and array2. Therefore, Marbles reports a memory leak for array1 and array2.

(cii) (1 points) **True / False**: Marbles incurred a false positive or false negative for p3, during the logging process.

- \bigcirc True
- False

ANSWER: True

Even though the code does not have a memory leak, we can see from the Marbles log file that Marbles did not report deallocation for array1 and array2, so the answer is True. This indicates a false positive (reported program leaked even though it did not).

(d) (2 points)

Describe a scenario where Marbles may produce false positives, and a scenario where it may produce false negatives. Please limit your entire answer to at most 4 sentences.

Your answer here.

ANSWER: False positives - Marbles reports memory leaked even though it did not. False negatives - Marbles reports memory didn't leak even though it did.

(e) (2 points)

Please explain at least one limitation of a dynamic analysis tool (which is assumed to be non-buggy) for identifying memory leaks. Limit your answer to at most 3 sentences.

Your answer here.

ANSWER: Answers may vary. Inability to detect compile time issues, limited support for early detection, slower than static analysis, and overhead are some examples of possible answers.

(f) (2 points)

Explain how a QA team might use a dynamic analysis tool to help test a multi-threaded program for race conditions. Additionally, list at least one pro and one con of using a dynamic analysis tool to detect race conditions. Limit your entire answer to at most five sentences.

Your answer here.

ANSWER: Student answers may vary. (For this question, please refer to "Q6f version 1" in Gradescope. "Q6f version 2" is not relevant to you.)

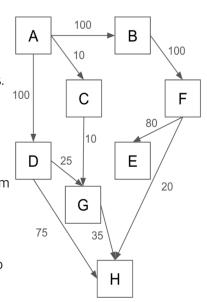

A dynamic analysis tool such as Eraser can help QA teams with identifying potential race condition behavior in large, multithreaded programs where static analysis (simply reading the code through code reviews, for instance) might be more cumbersome than usual. However, there may be inefficiency issues that a QA team must consider; lockset algorithms are considered to be rather inefficient in practice. Moreover, race conditions may not appear when using a dynamic analysis tool (heisenbugs as discussed in lecture). Not all race conditions may not be able to be detected when using a dynamic analysis tool.

(g) (3 points)

The QA team is now interested in profiling a program P, with the goal of understanding which execution paths are taken most frequently and how they can optimize P better on those paths.

After running the profiler, the team obtained a "path profile graph", which is shown to the right. Nodes in this graph represent disjoint portions of the program. An edge in this graph represents flow from one node (that represents a portion of P) to another. For instance, we have an edge from node A to node D in this graph for P. Assume program execution starts from node A.

The number labeled on an edge indicates the number of times that edge was executed. For instance, the edge from A to D has label 100. This means the profiler observed flows from A to D for 100 times, during the execution of P. Note that it does not matter for how long P was profiled, or how many times P was executed. All edge labels are normalized.

You want to figure out which path is the most frequently taken on P, so that you can optimize P on that path. Please list all possible paths P can take, based on the profile information, ordered from the most likely to be taken to least likely to be taken.

IMPORTANT: Please format your answer as a comma separated list, where each path is separated by a comma. An example answer entry would be formatted like: ABFH, ADGH (where ABFH is a path A->B->F->H).

Your answer here.

ANSWER: (For this question, please refer to "Q6g version 1" in Gradescope. "Q6g version 2" is not relevant to you.) ABFE, ADH, ADGH, ABFH, ACGH
